

Basin Deposits

Fluvial, eolian, spring, and paludal deposits that make up the valley-bottom fill in northern Pahump Valley. Settings range from active deposition to terraced and isolated deposits. Deposits are characteristically fine grained ranging from medium sands to clays, and ranging in consistency from loose to being indurated with gypsum or calcite. The basin floor is subject nearly daily to eolian processes, including the Spring Mountains also occasionally sweep across large portions of the valley bottom in broad sheets, modifying the landscape and depositing layers of fluvial sands and silts. The ages of basin deposits range from modern, active units to late Pleistocene deposits that are filled and exposed in the south-central part of the quadrangle.

Oba Active and intermittently active basin alluvium
Oba Active fluvial and eolian deposits on the floor of Pahump Valley. Light-brown silty sands, silts, and clays, with occasional flooding. **Obaj** deposits are similar to **Oba**, but are only intermittently active during large floods, and dominantly contain overbank and eolian sediments.

Obt Transitional basin-piedmont deposits
 Fine-grained fluvial and eolian silts and sands that form a transition zone between distal alluvial fans from the Nopah Range and fluvial deposits on the floor of Pahump Valley.

Qd Eolian dunes and deposits
Qd Light-brown, well-sorted, angular to rounded, non-cemented fine sands in active and partly stabilized dunes. Dunes are up to 5 m high. Latest Holocene age. **Qd7** Deposits are elongate landforms of clay, may be parra dunes.

Qbsc Colluvial deposits of the basin deposits of Browns Spring
 Generally clays, silts, and carbonate clasts, with some gravels near outcrops of **Qta**. These deposits are made up of colluvium eroded from the Basin deposits of Browns Spring (**Oba**), but may include deposits of the lower part of **Oba** that erode easily and are difficult to discern from colluvium.

Qbg Unit G
 Light-brown eolian silt, alluvial silts and muds, light-brown to light-gray alluvial sands. Most of the alluvial units are reworked from older basin deposits. Late Holocene deposits are up to 1 m thick.

Qbf Unit F
 Light-brown eolian silt, alluvial silts and muds, alluvial light-brown to light-gray sands. Much of the alluvial silts and muds are reworked from older basin deposits. This bedded to massive, deposits are friable and loose, and lack soil development. Deposits are as much as 1 to 2 m thick. Mid to late Holocene age. Radiocarbon dated at 5570±40 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). Four other subdivisions have been indicated below the upper part of the deposit. **Qbf1** to **Qbf4** indicate the upper part is light-brown silts, possibly local playa deposits. **Qbf5** indicates the upper part of the deposit is a brown clay or silt. **Qbf6** indicates the upper part is greenish tan silts of probable wet meadows origin. **Qbf7** indicates the upper part is light-brown silts, possibly local playa deposits. **Qbf8** indicates the upper part is a red-brown clay, derived from the breccia of the Bonanza King Formation at the southernmost end of the Montgomery Mountains.

Qbf9 Unit E
 Light-brown to yellowish-brown silt, light-brown to light-gray fine sandy silt, and locally light-green clayey silt or dark-brown silty clay. Thin bedded to massive. Typically 0.5 to 2 m thick, consisting of fluvial, eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qbd Unit D
 Light-gray to gray organic muds, light-brown to light-green clay, silt, fine sandy silt, marl, limestone, and locally brown clay. Interbeds and lenses of well sorted, cross bedded, pebbly gravel are common. Exposed thickness is typically 3 to 4 m, with a maximum of 6 m exposed in quarry walls in the Pahump Valley to the east. Generally consists of massive to thick bedded mud deposits; where consisting of predominantly silts and fine sands, units are thinly bedded and fissile. The upper 1 to 2 of this unit is characteristically light gray, calcareous mud that is partially cemented with calcite which weathers to curving and branching platy nodules. Top of the unit is commonly capped by a 30- to 50-cm-thick paludal limestone, that locally contains small mollusc, clam, and snail. Radiocarbon dated at 19,930±50 and 24,150±80 ybp on the Pahump Valley Quadrangle (dePolo and others, 1999).

Qbe7d/c Unit E or Unit D
 Deposits overlap by colluvium.

Qbe7d/c Unit E or Unit D
 Fine-grained basin deposit with a brown clay upper part that is similar to Unit **Obec**, but with small chunks of carbonate and marl littering the surface, which is more akin to Unit D.

Obs Basin deposits of Browns Spring
 Fine-grained, dark brown to light brown and white clay, silts, fine sands, marls, and limestones, with minor interbedded gravel. Thin to medium bedding. The deposits appear to be faulted or warped upwards along the Pahump Valley fault zone in the south central part of the quadrangle exposing them. A prominent, 0.5- to 1-m-thick paludal limestone caps many of the hills formed on the unit. These deposits are middle Pleistocene in age as constrained by thermoluminescence and U-series dating on the Mount Spring Quadrangle, indicating the unit is about 200 to 400 ka (Lundstrom and others, in prep.). Rancholabrean fossils have reportedly been found in this unit in the Stump Springs Quadrangle (Lundstrom and others, in prep.).

Qta Quaternary alluvium or late Tertiary
 Calcic-cemented gravels, sands, and ash that make up a northwest alignment of hills that are typically capped by the gravels. Gravels are dominantly composed of limestone clasts, with some volcanic and granitic clasts. These deposits appear to be derived from the south based on clast lithology and underlie the basin fill of Browns Spring in the southern part of Pahump Valley (Lundstrom and others, in prep.). The alignment of these hills is traverse to local drainages, and some drainages crossing Pahump Valley are deflected around the hills of **Qta** and **Obs**. The hills are aligned subparallel to the Pahump Valley fault zone, and may be tectonic upwarp. An ash was found below the cemented gravels on one hill that is presumably the ash mentioned by Matberg (1967). An ⁴⁰Ar/³⁹Ar date is pending.

Qbc Breccia of the southern Montgomery Mountains
 A breccia deposit made up of clasts predominantly derived from Bonanza King Formation, with some rare clasts of the underlying Stirling Quartzite incorporated into the lower part of the deposit. The unit appears to be deposited on hillslopes eroded on bedrock, and may be a landslide deposit. The source area has been tectonically removed in the Neogene.

Alluvial Fan Deposits

Sandy, coarse-pebble gravel alluvial fan deposits originating from the small set of hills projecting southward from the Montgomery Mountains and the northeastern flank of the Nopah Range. Includes poorly sorted, weak to moderately imbricated, generally clasts supported with minor matrix supported angular to subrounded gravel deposits. Thinly bedded to massive, with gravel lenses ranging from a few centimeters to 70 cm thick, and commonly 10 to 30 cm thick. Clasts are dominated by either limestones or quartzites depending on the source deposits. Some deposits, especially in the proximal areas, are thin beds (<0.5 m thick) overlying significantly older alluvial deposits. Deposits are middle Quaternary to late Holocene in age.

Qa Active alluvium
 Cobble, pebbly, sandy gravel within active washes with fans. Surface made up of anastomosing bar-and-swale microtopography, with no pavement or soil development. Subject to intermittent flooding in age.

Qc Surficial deposits
 Talus, debris, and fan surfaces in aprons around steep bedrock escarpments that are not part of the piedmont. Composed of boulders, cobbles, sands, and silts, and appears to span a large range in age, from latest Holocene to early Quaternary.

Qay Younger alluvium (undifferentiated)
 Fans and fan remnants characterized by surfaces ranging from subdued bar and channel to fully smoothed with moderately well developed desert pavements. Commonly includes earlier younger alluvium (**Qay1**), with interspersed later younger alluvium (**Qay2**) making delineation difficult. Latest Pleistocene to Holocene in age. Subject to intermittent flooding in places.

Qay1 Later younger alluvium
 Fan remnants characterized by subdued bar-and-swale microtopography, incipient desert pavement, weak rock varnish, and none to slight etching of limestone and dolomitic surface clasts. Soils typically A-C and A-B-C profiles with a 1- to 5-cm-thick, light-brown silt eolian epepion (**Av**), a 5- to 20-cm-thick, weak to non-existent calcic horizon (**Bk**) with Stage I carbonate development. Mid to late Holocene in age.

Qay2 Earlier younger alluvium
 Fan remnants characterized by tightly packed desert pavement, moderately developed rock varnish, incipient to moderate etching of surficial limestone and dolomitic clasts. Soils are typically A-B-C profiles with a 2- to 15-cm-thick, light brown eolian epepion (**Av**), a 10- to 20-cm-thick, slightly reddened, silt infiltrated, cambic horizon (**Bw**), and a 30-cm thick, calcic horizon with Stage II carbonate development. Latest Pleistocene to early Holocene in age.

Qai Intermediate age alluvium
 Fan-terrace remnants characterized by tightly packed desert pavement, dark rock varnish on non-carbonate clasts, and very strongly etched carbonate clasts. Flat-topped surfaces are quite prominent in this unit that is commonly well dissected, and elevated above surrounding fan surfaces. Unit typically contains a soil exhibiting a 5- to 10-cm-thick, light brown eolian silt epepion (**Av**), a 10- to 30-cm-thick, reddened and well-structured argillite horizon (**Bt**), and 100- to 150-cm-thick calcic horizon (**Bk**) with up to Stage IV carbonate. Upper soil horizons may be erosionally stripped in some areas. Late Pleistocene in age.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qai Intermediate age alluvium
 Fan-terrace remnants characterized by tightly packed desert pavement, dark rock varnish on non-carbonate clasts, and very strongly etched carbonate clasts. Flat-topped surfaces are quite prominent in this unit that is commonly well dissected, and elevated above surrounding fan surfaces. Unit typically contains a soil exhibiting a 5- to 10-cm-thick, light brown eolian silt epepion (**Av**), a 10- to 30-cm-thick, reddened and well-structured argillite horizon (**Bt**), and 100- to 150-cm-thick calcic horizon (**Bk**) with up to Stage IV carbonate. Upper soil horizons may be erosionally stripped in some areas. Late Pleistocene in age.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. Outcrops of massive calcic cementation eolian, and occasional paleosol deposits. Sediments are typically slightly indurated from compaction and light cementation of gypsum or calcite. Latest Pleistocene to Holocene in age. Correlative deposits have been radiocarbon dated at 10,270±270 ybp on the adjacent Pahump Valley Quadrangle (dePolo and others, 1999). The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Qao Older alluvium
 Fan-terrace remnants characterized by deep dissection and discordant rounded remnants (balcones), moderately to well-developed pavement with whitish calcareous litter abundant, and deeply etched carbonate clasts. The uppermost parts of these deposits are Holocene. Units labeled **Qbe** are undifferentiated Unit E deposits that are usually light-brown, fluvial or eolian, fine sandy silts.

Cambrian and Precambrian Sedimentary Rocks

Cambrian and Precambrian sedimentary rocks were compiled and modified from Burchfiel and others (1982). They include a faulted and broadly folded sequence of siliciclastic and carbonate rocks, principally quartzites and limestones.

Cbk Bonanza King Formation
Cbk The Bonanza King Formation is a limestone sequence that can be divided into a lower, massive limestone unit, and an upper group (Burchfiel and others, 1982). The lower member (**Cbk1**) consists of bedded, banded limestone, the Banded Mountain Member (Barnes and Palmer, 1961). Both members are significantly older alluvial deposits. Deposits are middle Quaternary to late Holocene in age.

Cc Carrara Formation
 The Carrara Formation is a transitional unit from the terrigenous sequence and the carbonate sequence below. It crops out at the base of a set of large hills that are largely made up of Bonanza King Formation, immediately above the alluvial apron. Thinly to very thickly bedded deposits of reddish-brown to gray siltstone, lime siltstone, and silty limestone. Erodes out into paper-like layers in places. Generally transitional and gradational contact with the overlying massive limestones of the Bonanza King Formation. The Carrara Formation is up to 446 m immediately west of the quadrangle (Burchfiel and others, 1982); the lower part of the Carrara Formation is buried by alluvium on the Sixmile Spring Quadrangle.

Cz Zabriskie Quartzite
 White, pink, red, and maroon vitreous quartzite. The formation is 80 to 90 m thick immediately to the west of the quadrangle (Burchfiel and others, 1982).

CZwc Wood Canyon Formation
 Dark-weathering sandstone, green, gray, and red shale; and siltstone with beds of brown-weathering sandy dolomite. This is the upper member of the Wood Canyon Formation as mapped by Burchfiel and others (1982). The Wood Canyon locally is 640 m thick (Burchfiel and others, 1982).

Zsu Stirling Quartzite
 The Stirling Quartzite has been divided into three members locally following Burchfiel and others (1982). A lower, middle, and upper member. The upper member (**Zsu**) consists of medium- to very coarse-grained and conglomeratic pink, gray, and white quartzite. Rare beds of light-brown sandy dolomite are present locally south of the Stewart Hill. The middle member (**Zsm**) consists of purple, maroon, and green shale and siltstone, interbedded with pink and red fine-grained quartzite. The middle member tends to form recessive slopes between the bounding, more resistant upper and lower members. The lower member (**Zsl**) consists pre-dominantly of fine- to coarse-grained and conglomeratic quartzite of white, gray, pink, maroon, and purple colors.

Zm Stirling Quartzite
 The Stirling Quartzite has been divided into three members locally following Burchfiel and others (1982). A lower, middle, and upper member. The upper member (**Zsu**) consists of medium- to very coarse-grained and conglomeratic pink, gray, and white quartzite. Rare beds of light-brown sandy dolomite are present locally south of the Stewart Hill. The middle member (**Zsm**) consists of purple, maroon, and green shale and siltstone, interbedded with pink and red fine-grained quartzite. The middle member tends to form recessive slopes between the bounding, more resistant upper and lower members. The lower member (**Zsl**) consists pre-dominantly of fine- to coarse-grained and conglomeratic quartzite of white, gray, pink, maroon, and purple colors.
